## Reading Material

## Example:

Consider the four matrices M1, M2, M3 and M4 having the dimensions as shown in Figure-4.

|             |             |
|-------------|-------------|
| M1: (10,20) | M3: (50,1)  |
| M2: (20,50) | M4: (1,100) |

FIGURE 4: MATRIX SIZES

Now the desired result is product of the four matrices -  $M1 \times M2 \times M3 \times M4$ . The simplest way of doing this would be to apply the normal matrix multiplication procedure recursively in the order

$$M1 \times (M2 \times (M3 \times M4))$$

Figure-5 shows the number of operations that are involved in performing this multiplication in the above order.

| Operation             | Multiplications | Total  |
|-----------------------|-----------------|--------|
| M3 X M4               | 50 X 100        | 5000   |
| M2 X (M3 X M4)        | 20 X 50 X 100   | 100000 |
| (M1 X M2 X (M3 X M4)) | 10 X 20 X 100   | 20000  |
|                       |                 | 125000 |

FIGURE 5: NORMAL MATRIX MULTIPLICATION

Here we see that the number of multiplication operations = 125000

Now we know that matrix multiplication is Associative. So,  $A \times B \times C = (A \times B) \times C = A \times (B \times C)$

This means that the same multiplication of the four matrices can also be performed in a different order to get the same result. Figure-6 shows an optimized solution to the same problem.
